AI Use and Design Rationale

The AI tool used:
In this Air Asia wire frame project I utilized Google’s Antigravity Hub 2.22v running model Gemini Flash 3.8 on medium context.

The prompt or prompts you used:
Prompts I used included -

- Analyze the project requirements.
- Define the purpose of each required page
- What are the required information, fields, buttons, and links
- What's the expected navigation and page flow
- What are the Gift Card table attributes needed for the Add and Update forms
- Ok now I'll ask you to break it all down on a page by page basis. Let's start with the login page.
- Is the air asia logo and "Air Asia Mileage Rewards Program" a defined requirement in the document?
- Feedback and adhereance to the requirements for the image that was provided for the login page
- Ok onto the card list requirements
- Check the card list image for requirements
- check the card add page for adhereance to requirements.
- Check the card-update
- Check the requirements of the new wireframe against the docs
- Create a PDF that arranges the images in the same format of the site map it has in the requirements document. Place it to a scale that a human can still read it but not so large it's hard to navigate.

A brief summary of how AI assisted your analysis or planning:
AI was able to aggregate the requirements scattered throughout the document for both the database requirements and visual requirements as I requested the requirements for each page.

One AI suggestion you verified, revised, or rejected after checking the requirements document:
AI suggested that I title a page Air Asia Mileage Rewards Program which it inferred should be the name. I decided that it was too specific for a wire frame and page branding and naming would come at a later stage so I opted to leave the pages defined as “Air Asia” instead.

A brief explanation, approximately 150 to 250 words, of how your wire frames support the system requirements:
I believe that the wire frames provided support the system requirements by first addressing the visual requirements located in the requirements use case table. Each use case defines a set of visual or page behaviors that are desired. Each of these were inferred by AI but manually checked for accuracy. The pages that required user input fields such as ‘add a customer’, ‘add a card’, or ‘update a card’ all have fields that align with the database field requirements. Additionally, each field defined throughout the document also lists the intended database value type such as an integer of length 11. When applicable I displayed fields that would match the value type. Buttons that are Administrative in nature or role based were highlighted to show a difference in user perspective based on the role based access control system we’re going to implement. The wire frame pdf itself has each individual wire frame labeled
